

Meningitis (bacterial) and meningococcal disease: recognition, diagnosis and management

[A1] Evidence review for symptoms and signs associated with bacterial meningitis

NICE guideline number tbc

Evidence review underpinning recommendations 1.1.1 to 1.1.4, 1.1.8 to 1.1.11, 1.1.16 to 1.1.17 and 1.2.1 to 1.2.2 in the NICE guideline

September 2023

Draft for consultation

This evidence review was developed by NICE

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

1 Symptoms and signs associated with 2 bacterial meningitis

3 Review question

4 What symptoms and signs, individually or in combination, are associated with bacterial
5 meningitis?

6 Introduction

7 Bacterial meningitis is a rare but serious infection, which can occur in any age group. Early
8 recognition of the condition requires a high index of suspicion. The diagnosis of bacterial
9 meningitis is frequently hindered by the non-specific nature of the early symptoms and signs,
10 which may mimic those found in other serious conditions or milder viral illnesses.

11 The aim of this review is to evaluate the symptoms and signs (and combinations thereof) that
12 are useful to healthcare professionals in deciding whether bacterial meningitis should be
13 considered in the initial differential diagnosis.

14 Summary of the protocol

15 See Table 1 for a summary of the Population, Risk markers, Comparison and Outcome
16 characteristics of this review.

17 **Table 1: Summary of the protocol**

Population	All adults, young people, children and babies (excluding neonates defined as aged 28 days old and younger) with suspected bacterial meningitis.
Risk markers	Any signs and symptoms, alone or in combination
Comparison	Binary accuracy data N/A Association data (if insufficient accuracy data) Absence of sign(s)/symptom(s)
Outcome	Critical Binary accuracy data <ul style="list-style-type: none">• Sensitivity for diagnosis of bacterial meningitis*• Specificity for diagnosis of bacterial meningitis* Association data (if insufficient accuracy data) <ul style="list-style-type: none">• Risk ratios for diagnosis of bacterial meningitis*• Odds ratios for diagnosis of bacterial meningitis* * Diagnosis of bacterial meningitis must be made based on lumbar puncture Important None

18 *N/A: Not applicable*

19 For further details see the review protocol in appendix A.

1 **Methods and process**

2 This evidence review was developed using the methods and process described in
3 [Developing NICE guidelines: the manual](#). Methods specific to this review question are
4 described in the review protocol in appendix A and the methods document (supplementary
5 document 1).

6 Declarations of interest were recorded according to [NICE's conflicts of interest policy](#).

7 **Diagnostic evidence**

8 **Included studies**

9 Sixteen studies were included in the diagnostic test accuracy review, 5 single-gate, cross-
10 sectional, diagnostic test accuracy (DTA) studies (Borchsenius 1991, Fretzayas 2010,
11 Krishna 1983, Lembo 1991, Walsh-Kelly 1992), 9 single-gate retrospective DTA studies
12 (Behrman 1989, De Cauwer 2007, Gowin 2017, Joffe 1983, Levy 1990, Magazzini 2012,
13 Magnussen 1980, Nielsen 1988, Oostenbrink 2001), and 2 two-gate, cross-sectional, DTA
14 studies (Bilavsky 2013, Brivet 2005). Studies with univariate analyses were included as no
15 studies with multivariate analyses were identified.

16 The included studies are summarised in Table 2.

17 Eleven studies included babies and children (Bilavsky 2013, De Cauwer 2007, Fretzayas
18 2010, Gowin 2017, Joffe 1983, Krishna 1983, Lembo 1991, Levy 1990, Nielsen 1988,
19 Oostenbrink 2001, Walsh-Kelly 1992); 2 studies included adults of any age (Brivet 2005,
20 Magazzini 2012) and 1 study only older adults (Behrman 1989); 1 study included older
21 children and adults and reported combined results (Magnussen 1980); and 1 study had an
22 undefined age range and reported results for the whole sample (Borchsenius 1991).

23 The signs and symptoms of bacterial meningitis in babies and children reported by the
24 studies can be categorised as follows: general signs of illness and duration of illness
25 (Bilavsky 2013, De Cauwer 2007, Joffe 1983, Krishna 1983, Levy 1990, Nielsen 1988,
26 Walsh-Kelly 1992); unusual, abnormal, or pale skin colour (Oostenbrink 2001); presence,
27 and type and size, of rash (De Cauwer 2007, Fretzayas 2010, Gowin 2017, Krishna 1983,
28 Nielsen 1988, Oostenbrink 2001); signs or symptoms of meningism (Bilavsky 2013, De
29 Cauwer 2007, Fretzayas 2010, Gowin 2017, Lembo 1991, Levy 1990, Nielsen 1988,
30 Oostenbrink 2001, Walsh-Kelly 1992); neurological deficits (Bilavsky 2013, De Cauwer 2007,
31 Gowin 2017, Joffe 1983, Krishna 1983, Levy 1990, Nielsen 1988, Oostenbrink 2001); altered
32 mental state (Krishna 1983, Nielsen 1988, Oostenbrink 2001); signs of shock (Walsh-Kelly
33 1992); respiratory symptoms (Fretzayas 2010, Krishna 1983); gastrointestinal symptoms and
34 food refusal (Bilavsky 2013, De Cauwer 2007, Fretzayas 2010, Gowin 2017, Krishna 1983,
35 Levy 1990, Nielsen 1988). One study also reported on the presence of one of a number of
36 signs/symptoms across categories (Joffe 1983). No studies reported on the distribution or
37 duration of rash, limb or body pain, or cardiac symptoms, as signs/symptoms of bacterial
38 meningitis in babies and children.

39 The signs and symptoms of bacterial meningitis in adults reported by the studies can be
40 categorised as follows: general signs of illness (Behrman 1989); signs or symptoms of
41 meningism (Behrman 1989, Magazzini 2012); neurological deficits (Behrman 1989, Brivet
42 2005, Magazzini 2012); altered mental state (Behrman 1989, Brivet 2005, Magazzini 2012);
43 signs of shock (Brivet 2005, Magazzini 2012). One study also reported on the presence of 1
44 of a number of signs/symptoms across categories (Brivet 2005). No studies reported on
45 unusual/abnormal/pale skin colour, or presence/type/size/distribution/duration of rash, or
46 limb/body pain, or cardiac or respiratory symptoms, or gastrointestinal symptoms or food
47 refusal, as signs/symptoms of bacterial meningitis in adults.

- 1 One study (Magnussen 1980) reported on fever, neck stiffness, headache, focal neurological
2 deficits, and altered mental state, as potential signs/symptoms of bacterial meningitis in older
3 children and adults.
- 4 One study (Borchsenius 1991) reported the following signs and symptoms of bacterial
5 meningitis in an undefined age range: reduced general condition; cyanosis; petechiae (≤ 4
6 mm); ecchymoses (>4 mm); neck stiffness; reduced consciousness; cold extremities; and
7 body pain.
- 8 One study restricted the reference standard to positive bacterial CSF culture (Bilavsky 2013).
9 One study attempted to restrict the reference standard to positive bacterial CSF culture but
10 included 1/10 where CSF culture was negative (Krishna 1983). One study used bacterial
11 pathogens identified in both CSF and blood cultures, CSF culture alone, or blood culture
12 alone as the reference standard, although the majority of patients had positive bacterial CSF
13 culture (95%; Brivet 2005). One study used CSF pleocytosis as the reference standard,
14 although 85% of those diagnosed with meningitis had positive CSF bacterial cultures (Joffe
15 1983). One study diagnosed bacterial meningitis based on high cell counts (predominantly
16 polymorphonuclear cells), low or normal sugar levels, and elevated protein, but reported that
17 for the majority of patients bacteria were recovered from the CSF culture (Levy 1990). One
18 study diagnosed bacterial meningitis based on positive CSF culture and/or CSF pleocytosis
19 and a positive blood culture, and 67% of the bacterial meningitis group had positive CSF
20 culture (De Cauwer 2007). One study used CSF Gram stain, CSF culture, other CSF
21 findings, or blood culture as the reference standard and included 36% of diagnoses made
22 without positive culture (Magnussen 1980). The following studies did not report details on the
23 proportion of the population diagnosed with CSF culture, but used a combination of CSF
24 culture and other methods as the reference standard: CSF culture, other CSF findings and/or
25 blood culture (Behrman 1989); CSF culture, blood culture, Gram stain, and/or PCR
26 (Fretzayas 2010); CSF culture, blood culture, and/or CSF leukocyte count (Borchsenius
27 1991, Oostenbrink 2001); CSF culture, CSF latex agglutination and/or Gram stain (Walsh-
28 Kelly 1992); CSF culture, CSF latex agglutination, Gram stain, and/or PCR (Gowin 2017);
29 CSF culture, or identification of specific bacterial antigen in combination with a positive Gram
30 stain of CSF in the absence of a positive culture (Lembo 1991). Two studies performed
31 lumbar puncture on all patients but did not report criteria for diagnosis or the proportion of the
32 population diagnosed with CSF culture (Magazzini 2012; Nielsen 1988).
- 33 Three studies compared those with bacterial meningitis to those with no meningitis (Bilavsky
34 2013, Borchsenius 1991, Joffe 1983). Six studies compared patients with bacterial meningitis
35 to those with viral meningitis (Brivet 2005, De Cauwer 2007, Gowin 2017, Magazzini 2012,
36 Magnussen 1980, Walsh-Kelly 1992). One study compared those with bacterial meningitis to
37 patients with other types of meningitis, including aseptic, tuberculous, suspected tuberculous,
38 fungal and viral meningitis (Behrman 1989). For 6 studies, the comparison was between
39 those with bacterial meningitis and a mixed comparison group including both those without
40 meningitis and those with other types of meningitis (Fretzayas 2010, Krishna 1983, Lembo
41 1991, Levy 1990, Nielsen 1988, Oostenbrink 2001).
- 42 Signs and symptoms were identified or reported by healthcare professionals in all 16 studies.
- 43 See the literature search strategy in appendix B and study selection flow chart in appendix C.
- 44 **Excluded studies**
- 45 Studies not included in this review are listed, and reasons for their exclusion are provided in
46 appendix J.
- 47 **Summary of included studies**
- 48 Summaries of the studies that were included in this review are presented in Table 2.

1 **Table 2: Summary of included studies**

Study	Population	Index test(s)	Reference standard(s)	Outcomes	Comments
Behrman 1989 Single-gate, cross-sectional (retrospective) DTA study US	N=50 Older adults (≥65 years) with the discharge diagnosis of meningitis, subdural empyema, brain abscess, or epidural abscess Bacterial meningitis, including partially treated bacterial meningitis (n=30) Other types of meningitis (n=20): Aseptic (n=3); tuberculous (n=3); suspected tuberculous (n=3); fungal (n=2); viral (n=1); unknown (n=8) 50 episodes of meningitis occurred in 48 patients: Age in years (mean; range in parentheses): 72 (65-89) Sex: male: 22 (46%); female: 26 (54%)	Signs and symptoms (taken from medical records): • Fever (≥37°C) • Meningismus • Headache • Change in mental status • Motor or cranial nerve deficits	Positive CSF culture or CSF examination revealing hypoglycorrhachia and/or CSF pleocytosis associated with a positive Gram's stain, a positive blood culture, or a positive counterimmunoelectrophoresis assay for Streptococcus pneumoniae, Neisseria meningitidis, or Haemophilus influenzae. Partially treated bacterial meningitis defined as results of CSF investigation showing pleocytosis, and evidence of bacterial otitis media or pneumonia in patients who received antibacterial therapy prior to lumbar puncture	• Sensitivity • Specificity	Causative organisms: Gram-positive (21/28; 75%): S. pneumoniae (12/28; 43%); Other streptococci, including Streptococcus bovis, Streptococcus viridans, Streptococcus faecalis, and S. pyogenes (4/28; 14%); Listeria monocytogenes (2/28; 7%); Staphylococci (2/28; 7%); Propionibacterium acnes (1/28; 4%). Gram-negative (7/28; 25%): Klebsiella species (2/28; 7%); Others, including Haemophilus influenzae, Enterobacter cloacae, Serratia species, Pseudomonas aeruginosa, and an undefined gram-negative rod (5/28; 18%)
Bilavsky 2013 Two-gate, cross-sectional DTA	N=86 Babies and children (3 months-17	Signs and symptoms in clinical history: • Fever (≥38°C)	Presence of a positive bacterial CSF culture	• Sensitivity • Specificity	Causative organisms: S. pneumoniae (23/40; 57.5%); N. meningitidis (17/40; 42.5%)

Study	Population	Index test(s)	Reference standard(s)	Outcomes	Comments
study Israel	years) with a confirmed diagnosis of bacterial meningitis compared with matched controls without a diagnosis of bacterial meningitis Bacterial meningitis (n=40): Age (in months): Median 27 (range 5-180); aged <12 months (n=7; 17%) Sex: male 19 (47.5%); female: 21 (52.5%) No meningitis (n=46) Age (in months): Median 24 (range 7-204); aged <12 months (n=10; 20.7%) Sex: male 29 (63%); female: 17 (37%)	<ul style="list-style-type: none"> • Nausea/vomiting • Headache • Convulsions <p>Signs and symptoms at presentation identified by healthcare professional:</p> <ul style="list-style-type: none"> • Fever (between 38°C and 39°C) • Fever ($\geq 39.1^\circ\text{C}$) • Nuchal rigidity • Brudzinski's sign • Kernig's sign • Kernig's sign and nuchal rigidity • Kernig's sign and Brudzinski's sign • Nuchal rigidity and Brudzinski's sign • Kernig's sign, nuchal rigidity, and Brudzinski's sign 			Excluded children treated with antibiotics prior to hospital admission, which may not reflect clinical practice

6 See the full evidence tables in appendix D and the forest plots in appendix E.

7 Summary of the evidence

8 This section is a narrative summary of the findings of the review, as presented in the GRADE
9 tables in appendix F. For details of the committee's confidence in the evidence and how this

1 affected recommendations, see The committee's discussion and interpretation of the
2 evidence.

3 The evidence was assessed as being high to very low quality, with the majority rated as low
4 or very low. Downgrading of the evidence was due to risk of bias and imprecision (95%
5 confidence intervals crossing decision making thresholds). No meta-analyses were
6 conducted for any of the index tests due to insufficient evidence after stratifying for age, and
7 the comparison group. For many of the index tests the evidence came from single studies
8 and all index tests were individual signs and symptoms (no multivariate analysis). See the
9 GRADE tables in appendix F for the certainty of the evidence for each individual outcome.

10 For interpreting the sensitivity and specificity estimates, the following rules of thumb were
11 used (as outlined in the review protocol in Appendix A): sensitivity/specificity estimates of at
12 least 90% were considered as very sensitive/specific; at least 50% as moderately
13 sensitive/specific; and less than 50% as not sensitive/specific.

14 ***Signs and symptoms of bacterial meningitis in babies and children***

15 **General signs of illness and duration of illness**

16 There was evidence that lethargy was both moderately to highly specific, and moderately to
17 highly sensitive, for a diagnosis of bacterial meningitis in babies and children.

18 Duration of symptoms of less than 24 hours was both a moderately specific and moderately
19 sensitive index test.

20 A toxic or ill appearance was a very specific, but not sensitive, symptom of bacterial
21 meningitis in babies and children. Irritability was a moderately to highly specific, but not
22 sensitive, symptom.

23 Fever (defined as a temperature over 39°C), visiting a physician within 48 hours, and a
24 duration of illness of over 2 days were moderately specific, but not sensitive, index tests of
25 bacterial meningitis in babies and children.

26 There was evidence that the clinical history including fever ($\geq 38^\circ\text{C}$) and a fever at clinical
27 presentation (threshold undefined) were very sensitive, but not specific, index tests for a
28 diagnosis of bacterial meningitis in babies and children.

29 Fever, defined as a temperature between 38°C and 39°C, was a moderately sensitive, but
30 not specific, sign of bacterial meningitis in babies and children.

31 **Unusual, abnormal, or pale skin colour**

32 There was some evidence that cyanosis was a very specific, but not sensitive, sign of
33 bacterial meningitis in babies and children.

34 **Presence, and type and size, of rash**

35 There was evidence that the presence of any rash, and a haemorrhagic rash, were very
36 specific, but not sensitive, index tests for bacterial meningitis in babies and children.

37 The evidence for petechiae was somewhat mixed, with studies with a comparator group
38 combining those with other types of meningitis and no meningitis showing petechiae to be a
39 very specific but not sensitive sign of bacterial meningitis in babies and children. While a
40 study with a viral meningitis comparator group showed petechiae to be neither specific nor
41 sensitive.

42 **Signs or symptoms of meningism**

43 There was inconsistent evidence for a composite factor of signs or symptoms of meningism,
44 which could not be explained by planned subgroup analyses. One study showed signs or

- 1 symptoms of meningism to be both moderately specific and moderately sensitive, and
2 another study showed this index test to be very sensitive but not specific for a diagnosis of
3 bacterial meningitis in babies and children.
- 4 There was some evidence showing Brudzinski's sign to be a generally moderately to highly
5 specific, and moderately sensitive, index test for a diagnosis of bacterial meningitis in babies
6 and children.
- 7 There was some evidence showing Kernig's sign to be a moderately to highly specific sign of
8 bacterial meningitis in babies and children, although the evidence for sensitivity was more
9 mixed (ranging from non-significant to moderately sensitive, and inconsistency cannot be
10 explained by planned subgroup analyses).
- 11 There was some evidence that Brudzinski's sign and Kernig's sign in combination, was a
12 very specific but not sensitive index test for a diagnosis of bacterial meningitis in babies and
13 children.
- 14 Neck stiffness was shown to be generally both moderately specific and moderately sensitive,
15 for a diagnosis of bacterial meningitis in babies and children. Neck strain was shown to be
16 moderately specific but not sensitive.
- 17 There was some evidence showing photophobia to be a very specific, but not sensitive,
18 symptom of bacterial meningitis in babies and children.
- 19 Bulging fontanelle was shown to be moderately to highly specific, but not sensitive, for a
20 diagnosis of bacterial meningitis in babies.
- 21 Neck stiffness and Brudzinski's sign in combination, was shown to be both moderately
22 specific and moderately sensitive.
- 23 Neck stiffness and Kernig's sign in combination, was shown to be very specific and
24 moderately sensitive for a diagnosis of bacterial meningitis in babies and children.
- 25 Presence of all 3 factors of Brudzinski's sign and Kernig's sign and neck stiffness, was a very
26 specific but not sensitive index test for bacterial meningitis in babies and children.
- 27 Presence of at least 1 of Brudzinski's sign or Kernig's sign or neck stiffness was both
28 moderately specific and moderately sensitive.
- 29 Evidence for headache was very mixed and inconsistency could not be explained by planned
30 subgroup analyses, estimates for both specificity and sensitivity ranged from non-significant
31 to a moderately useful index test.
- 32 Any symptom of CNS infection (irritability, lethargy, headache, or stiff neck) was very
33 sensitive, but not specific, for a diagnosis of bacterial meningitis in babies and children.
- 34 **Neurological deficits**
- 35 The following signs were very specific but not sensitive for a diagnosis of bacterial meningitis
36 in babies and children: focal neurological deficits; focal seizures; complex convulsions; and
37 convulsion without fever.
- 38 Seizure, and convulsions, were moderately to highly specific, but not sensitive, signs of
39 bacterial meningitis in babies and children.
- 40 The presence of any abnormal neurological finding was a very sensitive, and moderately
41 specific, index test for bacterial meningitis in babies and children.
- 42 Convulsion with fever was a moderately specific, but not sensitive, sign of bacterial
43 meningitis in babies and children.

1 **Altered mental state**

2 Evidence was mixed for reduced consciousness as a symptom of bacterial meningitis in
3 babies and children, and inconsistency could not be explained by planned subgroup
4 analyses. For specificity estimates ranged from non-significant to very specific, and for
5 sensitivity moderately to highly sensitive.

6 **Signs of shock**

7 There was some evidence that shock was a very specific, but not sensitive, index test for a
8 diagnosis of bacterial meningitis in babies and children.

9 **Respiratory symptoms**

10 The evidence for respiratory symptoms was mixed. One study showed respiratory symptoms
11 to be moderately specific but not sensitive, while another study showed high specificity and
12 moderate sensitivity, for bacterial meningitis in babies and children.

13 **Gastrointestinal symptoms and food refusal**

14 There was some evidence that gastrointestinal symptoms, and nausea, were both
15 moderately specific and moderately sensitive index tests for a diagnosis of bacterial
16 meningitis in babies and children.

17 The evidence for vomiting as a sign of bacterial meningitis in babies and children was mixed,
18 and the inconsistency could not be explained by planned subgroup analyses. Estimates for
19 both specificity and sensitivity ranged from non-significant to a moderately useful test.

20 Presence of nausea or vomiting was moderately to highly specific, and moderately sensitive,
21 for a diagnosis of bacterial meningitis in babies and children.

22 Constipation was a very specific, but not sensitive, symptom of bacterial meningitis in babies
23 and children.

24 Diarrhoea and loss of appetite were moderately specific, but not sensitive, index tests for
25 bacterial meningitis in babies and children.

26 **Cross-category signs and symptoms**

27 There was some evidence that the presence of any abnormal physical finding
28 (rash/petechiae, cyanosis, hypotension, or grunting respirations) was very specific, but not
29 sensitive, for a diagnosis of bacterial meningitis in babies and children:

30 The following index tests were both moderately specific and moderately sensitive: presence
31 of at least 1 of visit to physician within 48 hours or focal type of seizure; at least 1 of visit to
32 physician within 48 hours or seizure at presentation.

33 The following index tests were very sensitive and moderately specific for a diagnosis of
34 bacterial meningitis in babies and children: presence of at least 1 of visit to physician within
35 48 hours or abnormal neurologic finding; presence of at least 1 of focal seizure or abnormal
36 neurologic findings; presence of at least 1 of visit to physician within 48 hours, seizure, focal
37 seizure, abnormal physical finding (rash/petechiae, cyanosis, hypotension, or grunting
38 respirations), or abnormal neurologic findings.

39 Presence of at least 1 of focal seizure or abnormal physical finding (rash/petechiae,
40 cyanosis, hypotension, or grunting respirations) was a moderately specific, but not sensitive,
41 index test for a diagnosis of bacterial meningitis in babies and children.

42 ***Signs and symptoms of bacterial meningitis in adults***

43 **General signs of illness**

1 There was some evidence showing fever to be a very sensitive, but not specific, sign of
2 bacterial meningitis in adults.

3 **Signs or symptoms of meningism**

4 The following signs and symptoms were moderately sensitive but not specific for a diagnosis
5 of bacterial meningitis in adults: a composite factor of signs or symptoms of meningism; neck
6 stiffness; presence of at least 1 of Brudzinski's sign, or Kernig's sign, or neck stiffness.

7 Presence of 1 of Brudzinski's sign or Kernig's sign, and headache, were moderately specific
8 but not sensitive index tests for a diagnosis of bacterial meningitis in adults.

9 **Neurological deficits**

10 There was some evidence that focal neurological deficits, and neurological complaints, were
11 moderately to highly specific, but not sensitive, index tests for a diagnosis of bacterial
12 meningitis in adults.

13 Seizures were very specific, but not sensitive, for a diagnosis of bacterial meningitis in adults.

14 **Altered mental state**

15 There was some evidence showing altered mental state was a moderately to highly sensitive
16 symptom of bacterial meningitis in adults. The specificity estimates were more mixed (and
17 the inconsistency could not be explained by planned subgroup analyses) with estimates
18 ranging from not specific to very specific.

19 **Signs of shock**

20 Shock, and severe sepsis or shock, were very specific and moderately sensitive index tests
21 for a diagnosis of bacterial meningitis in adults.

22 **Cross-category signs and symptoms**

23 There was some evidence that the presence of at least 1 of altered mental status, or focal
24 neurological deficits, or seizures, or shock, was both very specific and very sensitive for a
25 diagnosis of bacterial meningitis in adults.

26 ***Signs and symptoms of bacterial meningitis in older children and adults***

27 Fever was both moderately specific and moderately sensitive for a diagnosis of bacterial
28 meningitis in older children and adults.

29 Focal neurological deficits, and altered mental state, were very specific but not sensitive
30 index tests for a diagnosis of bacterial meningitis in older children and adults.

31 Neck stiffness was moderately sensitive but not specific, for a diagnosis of bacterial
32 meningitis in older children and adults.

33 Headache was neither specific nor sensitive for a diagnosis of bacterial meningitis in older
34 children and adults.

35 ***Signs and symptoms of bacterial meningitis in an undefined age range***

36 Reduced general condition, and reduced consciousness, were very specific and moderately
37 sensitive index tests for a diagnosis of bacterial meningitis in an undefined age range.

38 The presence of petechiae, and neck stiffness, were both moderately specific and
39 moderately sensitive index tests of bacterial meningitis in an undefined age range.

40 Cyanosis, and cold extremities, were very specific but not sensitive signs of bacterial
41 meningitis in an undefined age range.

1 The presence of ecchymoses, and body pain, were moderately specific but not sensitive
2 index tests for a diagnosis of bacterial meningitis in an undefined age range.

3 See appendix F for full GRADE tables.

4 **Economic evidence**

5 **Included studies**

6 A single economic search was undertaken for all topics included in the scope of this
7 guideline, but no economic studies were identified which were applicable to this review
8 question.

9 **Economic model**

10 No economic modelling was undertaken for this review because the committee agreed that
11 other topics were higher priorities for economic evaluation. This was because this review
12 does not involve a comparison of competing courses of action.

13 **The committee's discussion and interpretation of the evidence**

14 **The outcomes that matter most**

15 The objective of this review was to assess the diagnostic accuracy of signs and symptoms
16 (index tests) to determine if a person presenting in the community or to hospital has bacterial
17 meningitis. The reference standard was a confirmed diagnosis of bacterial meningitis made
18 based on lumbar puncture. The committee considered the impact of true positives (correctly
19 identifying bacterial meningitis and starting the appropriate management), true negatives
20 (being able to provide reassurance that the person does not have bacterial meningitis), false
21 positives (potentially starting unnecessary treatments) and false negatives (failing to identify
22 people that require further interventions and intensive management). The committee agreed
23 that both sensitivity and specificity were important. Sensitivity was important as failing to
24 identify bacterial meningitis could lead to treatment being delayed until the condition worsens
25 with potentially serious implications (including death). Specificity was important, particularly
26 when considering signs and symptoms that might lead a clinician to *strongly* suspect
27 bacterial meningitis, as the misdiagnosis of bacterial meningitis would result in the initiation
28 of inappropriate treatment.

29 **The quality of the evidence**

30 The quality of the evidence ranged from high to very low, with the majority rated as low or
31 very low quality, and evidence was typically downgraded due to risk of bias (for example, it
32 was unclear if inappropriate exclusions were avoided or exclusions did not reflect clinical
33 practice, limited detail on how signs and symptoms defined and measured and index tests
34 often not systematically quantified, and unclear interval between index tests and reference
35 standard) and imprecision (95% confidence intervals crossing decision making thresholds).
36 For many of the index tests the evidence came from single studies and all index tests were
37 individual signs and symptoms (no multivariate analysis).

38 Evidence was found for: general signs of illness and duration of illness; unusual, abnormal,
39 or pale skin colour; presence and type and size of rash; signs or symptoms of meningism;
40 neurological deficits; signs of shock; body pain; respiratory symptoms; gastrointestinal
41 symptoms and food refusal.

42 No meta-analyses were conducted for any of the index tests due to insufficient evidence after
43 stratifying for age, and the comparison group.

1 **Benefits and harms**

2 The committee noted that all the evidence was based on individual signs and symptoms and
3 agreed that none of these signs or symptoms alone would be sufficient to make a diagnosis
4 of bacterial meningitis. The committee considered the evidence for sensitivity and specificity
5 of the individual signs and symptoms in this review and drew on their clinical knowledge and
6 experience to define combinations of signs and symptoms that might increase suspicion that
7 a person has bacterial meningitis.

8 The committee emphasised that bacterial meningitis is a rapidly evolving condition and can
9 be difficult to distinguish from other infections with similar signs and symptoms, and included
10 a recommendation that healthcare professionals should be aware of this and not use
11 individual signs and symptoms to rule bacterial meningitis in or out. The committee also
12 highlighted the importance that healthcare professionals are aware that bacterial meningitis
13 and meningococcal disease can occur at the same time, particularly in people with a rash
14 and included this in the recommendations. Based on their clinical knowledge and experience,
15 the committee highlighted that bacterial meningitis can present with non-specific symptoms
16 and signs particularly in young babies and older adults, and included this in the
17 recommendation to raise awareness.

18 The committee considered evidence showing that the presence of fever was largely
19 moderately to highly sensitive (but not specific), neck stiffness was shown to be generally
20 both moderately specific and moderately sensitive, reduced consciousness was shown to be
21 generally at least moderately specific and moderately sensitive, and altered mental state was
22 overall at least moderately specific and moderately sensitive, for a diagnosis of bacterial
23 meningitis. The evidence was mixed for the diagnostic accuracy of the presence of
24 headache, however, based on their clinical knowledge and experience, the committee
25 agreed that this symptom in combination with fever, neck stiffness and altered level of
26 consciousness or cognition, would raise the index of suspicion for bacterial meningitis. Given
27 the evidence showing at least moderate sensitivity and specificity for these individual signs
28 and symptoms, and their clinical knowledge and experience, the committee agreed that
29 fever, headache, neck stiffness and altered level of consciousness or cognition, should be
30 considered as a red flag combination for strongly suspecting that a person has bacterial
31 meningitis. However, the committee emphasised that bacterial meningitis may present with
32 non-specific symptoms particularly in young babies and older adults, and bacterial meningitis
33 should not be ruled out just because a person does not have one or more of the symptoms in
34 the red flag combination or can be strongly suspected based on clinical assessment even in
35 people who do not have the red flag combination. Based on their clinical knowledge and
36 experience the committee highlighted that the signs or symptoms included in the red flag
37 combination may be less common and/or harder to detect in certain ages and included notes
38 in the tables (of symptoms and signs) to raise awareness of the different ways in which
39 bacterial meningitis can present. Drawing on their experience and expertise, the committee
40 discussed that: headache cannot be reported by babies and young children and by those
41 with cognitive impairment; neck stiffness is less likely and harder to detect in babies and
42 older adults and in adults with cognitive impairment, dementia or arthritis, and in children
43 neck stiffness may present as more subtle discomfort or reluctance to move the neck;
44 photophobia is harder to identify in babies; fever is less common as a sign in babies and
45 older adults, and for young children other possible causes of fever should be considered in
46 line with relevant NICE guidance ([Fever in under 5s: assessment and initial management](#));
47 and bacterial meningitis may be missed in older adults with delirium or altered
48 consciousness, and in young people and young adults where altered level of consciousness
49 may be assumed to be caused by alcohol or substance misuse.

50 As discussed above, the committee noted that while people with bacterial meningitis may
51 present in the community or to hospital with the red flag combination (fever, headache, neck
52 stiffness and altered level of consciousness or cognition), if presenting early in the condition
53 or for babies and older adults, the person may only have non-specific features. Based on the

- 1 evidence reviewed and their clinical knowledge and experience, the committee included
2 signs and symptoms that may be associated with bacterial meningitis in tables for babies and
3 children, and for adults, and agreed based on expert consensus opinion that the more
4 features present the more likely it is that the person has bacterial meningitis.
- 5 There was some evidence that the presence of any rash, and a haemorrhagic rash, were
6 very specific (but not sensitive) index tests for a diagnosis of bacterial meningitis in babies
7 and children, and a petechial rash was both moderately specific and moderately sensitive for
8 a diagnosis of bacterial meningitis in an undefined age range. The committee emphasised
9 that a non-blanching rash is mainly associated with meningococcal disease with or without
10 meningococcal meningitis, and this was consistent with the evidence reviewed.
- 11 There was some evidence from babies and children and from an undefined age range that
12 cyanosis was a very specific (but not sensitive) sign of bacterial meningitis. The committee
13 agreed that these findings were consistent with their clinical experience that pale or unusual
14 skin colour (including cyanosis) can be associated with bacterial meningitis and they agreed
15 to include this sign in the recommendations but to maintain consistent terminology with the
16 NICE Fever in under 5s guideline (pale, mottled skin or cyanosis). The committee noted that
17 skin changes may be difficult to see on brown, black or tanned skin, and included this in the
18 notes section of the table to increase awareness for the healthcare professional who is
19 undertaking the physical examination. The committee noted that healthcare professionals
20 may need to check the conjunctivae (the membranes lining the inside of the eyelids and
21 covering the eyeballs) when checking for petechiae in people with darker skin.
- 22 The committee considered the evidence showing that a toxic or ill appearance was a very
23 specific (but not sensitive) symptom of bacterial meningitis in babies and children, and
24 reduced general condition was a very specific and moderately sensitive symptom in an
25 undefined age range, and agreed to include ill appearance as a symptom that might support
26 a diagnosis of bacterial meningitis.
- 27 There was some evidence that a bulging fontanelle was a moderately to highly specific (but
28 not sensitive) sign of bacterial meningitis in babies and this was included in the
29 recommendations as a sign that might increase the index of suspicion for bacterial meningitis
30 in babies and young children where the fontanelle is still open.
- 31 The committee considered the evidence showing that Brudzinski's sign was at least
32 moderately specific and moderately sensitive, and Kernig's sign was moderately to highly
33 specific (with more mixed sensitivity) for a diagnosis of bacterial meningitis in babies and
34 children, and presence of 1 of Brudzinski's sign or Kernig's sign was a moderately specific
35 (but not sensitive) index test in adults. However, the committee discussed that Kernig's and
36 Brudzinski's signs are very difficult to elicit, and in current clinical practice subtler
37 presentations of bacterial meningitis are more common. The committee emphasised that
38 these signs were introduced at a time when people presented after a few days and
39 antibiotics did not exist. The committee agreed not to include Kernig's or Brudzinski's signs in
40 the recommendations given how hard they are to elicit (particularly in babies), and that their
41 inclusion would take the focus away from other signs and symptoms that are more likely to
42 be helpful.
- 43 There was some evidence that irritability was a moderately to highly specific (but not
44 sensitive) symptom of bacterial meningitis in babies and children, and the committee agreed
45 to include irritability as a symptom that might be associated with bacterial meningitis
46 particularly in babies and young children. Drawing on their clinical knowledge and experience
47 the committee agreed that altered behaviour, particularly being unusually aggressive or
48 subdued, can be associated with bacterial meningitis in adults as well as babies and children
49 and highlighted that bacterial meningitis can be missed because delirium may be assumed to
50 be due to cognitive impairment in older adults, whereas altered behaviour may be attributed
51 to alcohol or substance misuse (rather than bacterial meningitis) in young people and young

- 1 adults. Based on expert clinical consensus the committee also agreed to include high-pitched
2 crying as a sign that might be associated with bacterial meningitis in babies.
- 3 The evidence showed that lethargy was at least moderately specific and moderately
4 sensitive for a diagnosis of bacterial meningitis in babies and children. Based on their clinical
5 knowledge and experience the committee agreed that lethargy can be associated with
6 bacterial meningitis at any age, but they highlighted that lethargy is often one of the non-
7 specific symptoms that babies, young children and older adults can present with and
8 included this in the recommendations.
- 9 There was some evidence showing that loss of appetite was a moderately specific (but not
10 sensitive) index test in babies and children and given the greater likelihood of a non-specific
11 presentation in babies this was included as a symptom that might be associated with
12 bacterial meningitis in this age group.
- 13 Respiratory symptoms were shown to be at least moderately specific (with more mixed
14 sensitivity estimates) for a diagnosis of bacterial meningitis in babies and children. There was
15 no evidence for respiratory symptoms in older age groups and based on their clinical
16 knowledge and experience the committee agreed that this was not a common symptom for
17 adults and should not be included in the recommendation for that age group. Based on
18 clinical expert consensus the committee agreed to include tachypnoea (raised respiratory
19 rate), apnoea (slowed or stopped breathing), and grunting as specific respiratory symptoms
20 that may support the diagnosis of bacterial meningitis in babies and children.
- 21 There was some evidence that shock was a very specific, but not sensitive, index test for a
22 diagnosis of bacterial meningitis in babies and children. Shock, and severe sepsis or shock,
23 were also very specific (and moderately sensitive) index tests for a diagnosis of bacterial
24 meningitis in adults. There was also some evidence from an undefined age range that cold
25 extremities were a very specific (but not sensitive) sign of bacterial meningitis. Based on this
26 evidence and their clinical knowledge and experience the committee included cardiovascular
27 indications of shock, such as cold hands and feet or other early signs of sepsis, as signs that
28 might support a diagnosis of bacterial meningitis in babies, children, and adults.
- 29 The committee considered evidence showing photophobia to be a very specific, but not
30 sensitive, symptom of bacterial meningitis in babies and children. Based on their clinical
31 knowledge and experience, the committee agreed that photophobia can also be associated
32 with bacterial meningitis in older age groups. The committee included photophobia as a
33 symptom that might support the diagnosis of bacterial meningitis in babies, children, and
34 adults, but highlighted that this can be harder to identify in babies.
- 35 Evidence showed that focal neurological deficits were at least moderately specific (but not
36 sensitive) signs of bacterial meningitis in babies and children, adults, and a combined older
37 children and adult population, and the committee agreed to include focal neurological deficits
38 in the recommendations.
- 39 There was also some evidence that focal seizures and seizures were at least moderately
40 specific (but not sensitive) signs of bacterial meningitis in babies and children. Seizures were
41 also shown to be a very specific (but not sensitive) index test in adults. Based on this
42 evidence, and their clinical knowledge and experience, the committee agreed to include
43 seizures as a sign that might support a diagnosis of bacterial meningitis for all age groups.
- 44 The evidence for vomiting as a sign of bacterial meningitis in babies and children was mixed
45 with estimates ranging from non-significant to a moderately useful test for both specificity and
46 sensitivity. There was no evidence for vomiting in adults. The committee agreed that vomiting
47 was not reliably associated with a diagnosis of bacterial meningitis. However, given the
48 variability in the symptoms that people present with, the committee included vomiting as a
49 non-specific symptom that might support a diagnosis of bacterial meningitis for any age

1 group but considered the position towards the bottom of the tables (of signs and symptoms)
2 as appropriate based on the evidence and their expert clinical opinion.

3 There was some evidence showing body pain was a moderately specific (but not sensitive)
4 index test for a diagnosis of bacterial meningitis in an undefined age range. Based on clinical
5 expert consensus the committee agreed to include limb, back and abdominal pain as
6 examples of unexplained body pain that may support the diagnosis of bacterial meningitis in
7 any age group.

8 The committee took into account the rapidly evolving nature of bacterial meningitis, and that
9 people can present with subtle signs or symptoms that might be missed if not considered in
10 the context of the patient's usual state. Based on their clinical knowledge and experience the
11 committee agreed that for people with reduced consciousness or communication difficulties it
12 was important that family members or carers are asked about recent changes in symptoms.

13 Given the potentially serious implications of a delay to treatment (including death), the
14 committee agreed based on expert clinical consensus that people with suspected bacterial
15 meningitis should be transferred to hospital as an emergency, and the hospital should be
16 alerted and informed that an assessment by a senior clinical decision maker will be required.

17 The committee agreed that it was also important to provide safety netting for people returning
18 home after a clinical assessment for bacterial meningitis. Based on their clinical knowledge
19 and experience and considering the rapidly evolving nature of bacterial meningitis, the
20 committee agreed that a safety netting arrangement should be considered, and people
21 should be told what to do if they develop new symptoms, if a rash changes from blanching to
22 non-blanching or if existing symptoms or signs get worse (namely, return to the GP or ring
23 NHS 111 or 999). The committee also wanted to raise awareness that although a person
24 might not have bacterial meningitis, they may have another serious condition. The committee
25 specifically wanted to highlight sepsis and pneumonia, but also intracranial bleed or
26 ischaemia that is often overlooked, as potential alternative diagnoses.

27 **Cost effectiveness and resource use**

28 This review question did not consider decisions between competing alternatives and
29 therefore is not directly relevant to the tools of economic evaluation. The recommendations
30 primarily provide advice to health care professionals on the recognition and diagnosis of
31 bacterial meningitis rather than specific courses of action. However, the committee
32 considered that early and correct identification of bacterial meningitis was a prerequisite of
33 cost-effective management. They also reflected that the recommendations largely reinforce
34 current best practice and knowledge and therefore they did not believe they would have a
35 significant resource impact.

36 **Recommendations supported by this evidence review**

37 This evidence review supports recommendations 1.1.1 to 1.1.4, 1.1.8 to 1.1.11, 1.1.16 to
38 1.1.17 and 1.2.1 to 1.2.2. Other evidence supporting these recommendations can be found in
39 the evidence review on symptoms and signs associated with meningococcal disease [A3].

2 Appendix A Review protocols

3 **Table 3: Review protocol**

Field	Content
PROSPERO registration number	CRD42021245975
Review title	Symptoms and signs associated with bacterial meningitis
Review question	What symptoms and signs, individually or in combination, are associated with bacterial meningitis?
Objective	To determine the signs and symptoms (individually or in combination) that are associated bacterial meningitis
Searches	<p>The following databases will be searched:</p> <ul style="list-style-type: none">EmbaseMEDLINECochrane Central Register of Controlled Trials (CENTRAL)Cochrane Database of Systematic Reviews (CDSR) <p>Searches will be restricted by:</p> <ul style="list-style-type: none">Date limitations: No date limitEnglish languageHuman studies <p>The full search strategies for MEDLINE database will be published in the final review. For each search, the principal database search strategy is quality assured by a second information scientist using an adaptation of the PRESS 2015 Guideline Evidence-Based Checklist.</p>
Condition or domain being studied	Bacterial meningitis
Population	<p>Inclusion: All adults, young people, children and babies (excluding neonates defined as aged 28 days old and younger) with suspected bacterial meningitis</p> <p>Exclusion:</p>

Field	Content
	<p>People:</p> <ul style="list-style-type: none"> • with known immunodeficiency • who have brain tumours, pre-existing hydrocephalus, intracranial shunts, previous neurosurgical procedures, or known cranial or spinal anomalies that increase the risk of bacterial meningitis • with confirmed viral meningitis or viral encephalitis • with confirmed tuberculous meningitis • with confirmed fungal meningitis <p>Note. The meningitis exclusion criteria applies to those that are identified as having condition of interest (bacterial meningitis), but may be included in the population that were not identified as having bacterial meningitis.</p>
Risk markers	Any signs and symptoms, alone or in combination
Comparator/Reference standard/Confounding factors for prognostic estimates	<p>1. Binary accuracy data: N/A</p> <p>2. Association data (if insufficient accuracy data): Absence of sign(s)/symptom(s)</p>
Types of study to be included	<p>1. Binary accuracy data</p> <ul style="list-style-type: none"> • Systematic reviews of cross-sectional diagnostic accuracy studies. • Individual cross-sectional diagnostic accuracy studies. <p>Studies with prospective and retrospective data collection will be included. Two-gate studies will only be included if there are insufficient single-gate studies for a given sign, symptom or combination)</p> <p>Conference abstracts will not be considered.</p> <p>2. Association data (if insufficient accuracy data for a given sign, symptom or combination)</p> <ul style="list-style-type: none"> • Systematic reviews • Prospective cohort studies with multivariate analyses

Field	Content
	<ul style="list-style-type: none"> • If insufficient prospective cohort studies: retrospective cohort studies with multivariate analyses <p>Studies with univariate analyses will only be included if there are insufficient studies with multivariate analyses for a given sign, symptom or combination.</p> <p>Non-randomised studies will be downgraded for risk of bias if they do not adequately adjust for the following covariates, but will not be excluded for this reason: age (if not possible to stratify)</p> <p>Conference abstracts will not be considered.</p>
Other exclusion criteria	<p>Countries other than OECD high income countries</p> <p>Studies published not in English-language</p>
Context	<p>This guidance will fully update the following: Meningitis (bacterial) and meningococcal septicaemia in under 16s: recognition, diagnosis and management (CG102)</p>
Primary outcomes (critical outcomes)	<p>1. Binary accuracy data</p> <ul style="list-style-type: none"> • Sensitivity for diagnosis of bacterial meningitis* • Specificity for diagnosis of bacterial meningitis* <p>2. Association data (if insufficient accuracy data)</p> <ul style="list-style-type: none"> • Risk ratios for diagnosis of bacterial meningitis* • Odds ratios for diagnosis of bacterial meningitis* <p>* Diagnosis of bacterial meningitis must be made based on lumbar puncture</p>
Secondary outcomes (important outcomes)	N/A
Data extraction (selection and coding)	<p>All references identified by the searches and from other sources will be uploaded into STAR and de-duplicated. Titles and abstracts of the retrieved citations will be screened to identify studies that potentially meet the inclusion criteria outlined in the review protocol. 5% of the abstracts will be reviewed by two reviewers, with any disagreements resolved by discussion or, if necessary, a third independent reviewer. Full versions of the selected studies will be obtained for assessment. Studies that fail to meet the inclusion criteria once the full version has been checked will be excluded at this stage. Each study excluded after checking the full version will be listed, along with the reason for its</p>

Field	Content
	<p>exclusion. A standardised form will be used to extract data from studies. The following data will be extracted: study details (reference, country where study was carried out, type and dates), participant characteristics, inclusion and exclusion criteria, details of the signs and symptoms, setting and follow-up, relevant outcome data and source of funding. One reviewer will extract relevant data into a standardised form, and this will be quality assessed by a senior reviewer.</p>
Risk of bias (quality) assessment	<p>Quality assessment of individual studies will be performed using the following checklist:</p> <ul style="list-style-type: none"> • ROBIS tool for systematic reviews • QUADAS-2 tool for diagnostic test accuracy studies <p>Quality in Prognostic Studies (QUIPS) tool for prognostic studies The quality assessment will be performed by one reviewer and this will be quality assessed by a senior reviewer.</p>
Strategy for data synthesis	<p>Binary accuracy data</p> <p>Where data is available from two or more studies for the same parameter and is sufficiently consistent, meta-analysis of diagnostic test accuracy will be performed using the metandi and midas applications in STATA/winbugs and Cochrane Review Manager software.</p> <p>Sensitivity and specificity with 95% CIs will be used as outcomes for diagnostic test accuracy. These diagnostic accuracy parameters will be obtained from the studies or calculated by the technical team using data from the studies.</p> <p>Association data</p> <p>Quantitative findings will be formally summarised in the review. Where multiple studies report on the same factors and the definitions used and approach to analysis in the primary papers is sufficiently consistent, meta-analyses will be conducted using Cochrane Review Manager software. A fixed effect meta-analysis will be conducted and data will be presented as risk ratios if possible or odds ratios when required (for example if only available in this form in included studies). Heterogeneity in the effect estimates of the individual studies will be assessed by visual inspection of the forest plots and consideration of the I² statistic. Heterogeneity will be explored as appropriate using sensitivity analyses and pre-specified subgroup analyses. If heterogeneity cannot be explained through subgroup analysis then a random effects model will be used for meta-analysis, or the data will not be pooled if the random effects model does not adequately address heterogeneity.</p> <p>The confidence in the findings across all available evidence will be evaluated for each outcome using</p>

Field	Content
	<p>an adaptation of the 'Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox' developed by the international GRADE working group: http://www.gradeworkinggroup.org/</p> <p>Minimally important differences: Decision making thresholds (for binary accuracy data)</p> <ul style="list-style-type: none"> • Sensitivity: <ul style="list-style-type: none"> ○ Very useful test: $\geq 90\%$ ○ Moderately useful test: $\geq 50\%$ ○ Not a useful test $< 50\%$ • Specificity: <ul style="list-style-type: none"> ○ Very useful test: $\geq 90\%$ ○ Moderately useful test: $\geq 50\%$ ○ Not a useful test $< 50\%$ <p>Minimally important differences (for association data)</p> <ul style="list-style-type: none"> ○ Strong association: < 0.5 and > 2.00 ○ Moderate association: < 0.80 and > 1.25 ○ Small association: any statistically significant association ○ No association: no statistically significant association
Analysis of sub-groups	<p>Evidence will be stratified by: Stratifications:</p> <ul style="list-style-type: none"> • Population that do not receive a diagnosis of bacterial meningitis: <ul style="list-style-type: none"> ○ Viral, tuberculous or fungal meningitis ○ Absence of meningitis • Person identifying signs/symptoms: <ul style="list-style-type: none"> ○ Healthcare professionals ○ Non-healthcare professionals • Age: <ul style="list-style-type: none"> ○ Younger Infants: > 28 days to ≤ 3 months of age

Field	Content	
	<ul style="list-style-type: none"> ○ Older infants: >3 months to <1 year of age ○ Children: ≥1 year to <18* years of age ○ Adults: ≥18* years of age <p>*There is variation in clinical practice regarding the treatment of 16 to 18 year olds. Therefore, we will be guided by cut-offs used in the evidence when determining if 16 to 18 year olds should be treated as adults or children.</p> <p>Evidence will be subgrouped by the following only in the event that there is significant heterogeneity in outcomes:</p> <ul style="list-style-type: none"> ● Age: <ul style="list-style-type: none"> ○ Young and middle aged adults ○ Older adults* ● Population that do receive a diagnosis of meningococcal disease: <ul style="list-style-type: none"> ○ Non-specific meningococcal disease ○ Meningococcal disease excluding meningitis alone <p>*There is variation regarding the age at which adults should be considered older adults. Therefore, we will be guided by cut-offs used in the evidence when determining this threshold.</p> <p>Where evidence is stratified or subgrouped the committee will consider on a case by case basis if separate recommendations should be made for distinct groups. Separate recommendations may be made where there is evidence of a differential effect of interventions in distinct groups. If there is a lack of evidence in one group, the committee will consider, based on their experience, whether it is reasonable to extrapolate and assume the interventions will have similar effects in that group compared with others.</p>

	Named contact e-mail: meningitis&meningococcal @nice.org.uk		
	Organisational affiliation of the review: National Institute for Health and Care Excellence (NICE) and National Guideline Alliance		
Review team members	National Guideline Alliance		
Funding sources/sponsor	This systematic review is being completed by the National Guideline Alliance which receives funding from NICE.		

Field	Content	
Conflicts of interest	All guideline committee members and anyone who has direct input into NICE guidelines (including the evidence review team and expert witnesses) must declare any potential conflicts of interest in line with NICE's code of practice for declaring and dealing with conflicts of interest. Any relevant interests, or changes to interests, will also be declared publicly at the start of each guideline committee meeting. Before each meeting, any potential conflicts of interest will be considered by the guideline committee Chair and a senior member of the development team. Any decisions to exclude a person from all or part of a meeting will be documented. Any changes to a member's declaration of interests will be recorded in the minutes of the meeting. Declarations of interests will be published with the final guideline.	
Collaborators	Development of this systematic review will be overseen by an advisory committee who will use the review to inform the development of evidence-based recommendations in line with section 3 of Developing NICE guidelines: the manual . Members of the guideline committee are available on the NICE website: https://www.nice.org.uk/guidance/indevelopment/gid-ng10149 .	
Other registration details	None	
Reference/URL for published protocol	https://www.crd.york.ac.uk/PROSPERO/display_record.php?RecordID=245975	
Dissemination plans	<p>NICE may use a range of different methods to raise awareness of the guideline. These include standard approaches such as:</p> <ul style="list-style-type: none"> • notifying registered stakeholders of publication • publicising the guideline through NICE's newsletter and alerts • issuing a press release or briefing as appropriate, posting news articles on the NICE website, using social media channels, and publicising the guideline within NICE

Appendix B Literature search strategies

Literature search strategies for review question: What symptoms and signs, individually or in combination, are associated with bacterial meningitis?

Clinical Search

This was a combined search to cover both this review (A1) and also evidence reviews on signs and symptoms and risk factors associated with meningococcal disease (A3 and A4); and risk factors associated with bacterial meningitis (A2).

Database(s): Medline & Embase (Multifile) – OVID interface

Embase Classic+Embase 1947 to 2022 November 07, Ovid MEDLINE(R) ALL 1946 to November 07, 2022

8 Study details

Country/ies where study was carried out	US
Study type	Single-gate, cross-sectional (retrospective) DTA study
Study dates	1970 to 1985
Inclusion criteria	Older adults (≥ 65 years) with the discharge diagnosis of meningitis, subdural empyema, brain abscess, or epidural abscess
Exclusion criteria	Not reported
Patient characteristics	N=50 Bacterial meningitis, including partially treated bacterial meningitis (n=30) Causative organisms: Gram-positive (21/28; 75%): <i>S. pneumoniae</i> (12/28; 43%); Other streptococci, including <i>Streptococcus bovis</i> , <i>Streptococcus viridans</i> , <i>Streptococcus faecalis</i> , and <i>S pyogenes</i> (4/28; 14%); <i>Listeria monocytogenes</i> (2/28; 7%); <i>Staphylococci</i> (2/28; 7%); <i>Propionibacterium acnes</i> (1/28; 4%). Gram-negative (7/28; 25%): <i>Klebsiella</i> species (2/28; 7%); Others, including <i>Haemophilus influenzae</i> , <i>Enterobacter cloacae</i> , <i>Serratia</i> species, <i>Pseudomonas aeruginosa</i> ,

	<p>and an undefined gram-negative rod (5/28; 18%).</p> <p>Other types of meningitis (n=20): Aseptic (n=3); tuberculous (n=3); suspected tuberculous (n=3); fungal (n=2); viral (n=1); unknown (n=8)</p> <p>50 episodes of meningitis occurred in 48 patients:</p> <p>Age in years (mean; range in parentheses): 72 (65-89)</p> <p>Sex: male: 22 (46%); female: 26 (54%)</p>
Index test(s)	<p>Signs and symptoms (taken from medical records):</p> <p>(a) Fever (defined as a rectal temperature of at least 37°C documented on the patient's medical record or the patient's history of fever at home)</p> <p>(b) Meningismus</p> <p>(c) Headache</p> <p>(d) Change in mental status</p> <p>(e) Motor or cranial nerve deficits</p>
Reference standard(s)	<p>Positive CSF culture or CSF examination revealing hypoglycorrachia and/or CSF pleocytosis associated with a positive Gram's stain, a positive blood culture, or a positive counterimmunoelectrophoresis assay for <i>Streptococcus pneumoniae</i>, <i>Neisseria meningitidis</i>, or <i>Haemophilus influenzae</i>.</p> <p>Partially treated bacterial meningitis defined as results of CSF investigation showing pleocytosis, and evidence of bacterial otitis media or pneumonia in patients who received antibacterial therapy prior to lumbar puncture</p>
Duration of follow-up	Not reported
Sources of funding	Not reported

1 Abbreviations: CSF: cerebrospinal fluid; DTA: diagnostic test accuracy; *N. Meningitidis*: *Neisseria Meningitidis*; *S. pneumoniae*: *Streptococcus pneumoniae*

2

3 **Critical appraisal - QUADAS-2**

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Unclear <i>(Records of all eligible patients admitted during study period reviewed, but unclear if the study avoided inappropriate exclusions (exclusion criteria not reported))</i>
Patient selection: applicability	Are there concerns that included patients do not match the review question?	Low
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	High <i>(No information about whether index tests were interpreted without knowledge of the reference standard, index tests poorly defined, and retrospective study over 15</i>

Section	Question	Answer
		<i>years with various investigators assessing signs and symptoms without clear definitions)</i>
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	High <i>(Reference standard CSF culture, other CSF findings or blood culture. No details on proportion of population diagnosed with CSF culture)</i>
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Unclear <i>(Unclear interval between index test and reference standard)</i>

4 **Study details**

Country/ies where study was carried out	Israel
Study type	Two-gate, cross-sectional DTA study

	Babies and children with a confirmed diagnosis of bacterial meningitis compared with matched controls without a diagnosis of bacterial meningitis.
Study dates	January 2001 to December 2004
Inclusion criteria	Babies and children aged 3 months to 17 years diagnosed with bacterial meningitis. The control group included children who underwent lumbar puncture with a suspicion of meningitis, but were eventually diagnosed with diseases other than bacterial or aseptic meningitis.
Exclusion criteria	Antibiotic treatment before arrival to the emergency department
Patient characteristics	N=86 Bacterial meningitis (n=40) Age (in months): Median 27 (range 5-180); aged <12 months (n=7; 17%) Sex: male 19 (47.5%); female: 21 (52.5%) Causative species: <i>S. pneumoniae</i> (N=23; 57.5%), and <i>N. Meningitidis</i> (N=17; 42.5%). No meningitis (n=46) Age (in months): Median 24 (range 7-204); aged <12 months (N=10; 20.7%) Sex: male 29 (63%); female: 17 (37%)
Index test(s)	Signs and symptoms in clinical history: (a) Clinical history included fever ($\geq 38^{\circ}\text{C}$) (b) Clinical history included nausea/vomiting (c) Clinical history included headache

	<p>(d) Clinical history included convulsions</p> <p>Signs and symptoms at presentation identified by healthcare professional:</p> <p>(a) Fever (between 38°C and 39°C)</p> <p>(b) Fever ($\geq 39.1^\circ\text{C}$)</p> <p>(c) Nuchal rigidity</p> <p>(d) Brudzinski’s sign</p> <p>(e) Kernig’s sign</p> <p>(f) Presence of 2 factors (Kernig’s sign and nuchal rigidity)</p> <p>(g) Presence of 2 factors (Kernig’s sign and Brudzinski’s sign)</p> <p>(h) Presence of 2 factors (nuchal rigidity and Brudzinski’s sign)</p> <p>(i) Presence of 3 factors (Kernig’s sign, nuchal rigidity, and Brudzinski’s sign)</p>
Reference standard(s)	Presence of a positive bacterial CSF culture
Duration of follow-up	Not reported
Sources of funding	Not reported (no conflicts of interest reported)

1 Abbreviations: CSF: cerebrospinal fluid; DTA: diagnostic test accuracy; N. Meningitidis: Neisseria Meningitidis; S. pneumoniae: Streptococcus pneumoniae

4 **Study details**

Country/ies where study was carried out	Norway
Study type	Single-gate, cross-sectional DTA study (a very small number of patients [5% of full sample that included those with meningococcal disease] included retrospectively)
Study dates	December 1981 to April 1982
Inclusion criteria	Patients with suspected systemic meningococcal disease admitted to hospital (those with meningitis only are included in this review, and those with septicemia or meningitis and septicemia are included in the review on signs and symptoms of

	<p>meningococcal disease).</p> <p>The control group (n=61) included those where meningococcal disease could be ruled out (with n=2 who were difficult to categorize included in the control group as meningitis of unknown microbiological etiology). For this review, the control participants (n=25) with bacterial meningitis or septicemia (excluding those due to <i>N. meningitidis</i>) and other bacterial infections were not included.</p>
Exclusion criteria	Not reported
Patient characteristics	<p>N=92</p> <p>Meningococcal meningitis (n=56):</p> <p>Age: Reported for whole sample only (including those with meningococcal disease); Mean/median not reported; 50% aged < 12 years.</p> <p>No meningococcal or bacterial infection (n=36):</p> <p>Age: Reported for whole sample only (including control participants not included in this review; Mean/median not reported; 79% aged < 12 years</p> <p>Viral infections (positive viral isolation or serious meningitis; n=14); other diseases (n=22; includes n=15 with upper respiratory tract infections of unknown aetiology). n=2 who were difficult to categorize included in the control group as meningitis of unknown microbiological aetiology).</p>
Index test(s)	<p>Signs and symptoms recorded by healthcare professional on the day of admission to hospital:</p> <p>(a) Petechiae (≤ 4mm)</p> <p>(b) Reduced general condition</p> <p>(c) Ecchymoses (cutaneous haemorrhages >4 mm)</p> <p>(d) Reduced consciousness</p>

	(e) Cold extremities
	(f) Cyanosis
	(g) Neck stiffness
	(h) Body pain
Reference standard(s)	Method of diagnosis was reported for the whole sample only (including those with meningococcal disease): growth of meningococci in blood and/or CSF (for 62%), or based on the clinical picture, meningococcal antigen in CSF, or growth of <i>N. meningitidis</i> in pharyngeal swab specimens (for 38%).
Duration of follow-up	Not reported
Sources of funding	Not reported
Other information	Data was not reported for clinical symptoms that were non-significant (presence of convulsions, back rigidity, headache, nausea, chills, fever, diarrhoea, irritability, systolic blood pressure <100, heart rate ≥ 120 , rectal temperature ≥ 40.0)

1 Abbreviations: CSF: cerebrospinal fluid; DTA: diagnostic test accuracy; *N. Meningitidis*: *Neisseria Meningitidis*

3 **Critical appraisal - QUADAS-2**

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Unclear <i>(Generally a consecutive sample enrolled (5% included retrospectively), but exclusion criteria not reported. Inclusion criteria limited to patients hospitalized with suspected systemic meningococcal disease, but no further details reported.)</i>
Patient selection: applicability	Are there concerns that included patients do not match the review question?	Low

Section	Question	Answer
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	High <i>(No information about whether index tests were interpreted without knowledge of the reference standard, and no detail on how clinical features measured and many of these factors are subjective (for example, reduced general condition and reduced consciousness). Data not reported for non-significant signs and symptoms)</i>
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	High <i>(Study includes patients without bacteriological proof (N=44, 38% of the full sample that includes those with meningitis only), and in the full sample there is a statistically significant difference between these patients and those with growth of N. meningitidis from CSF or blood in terms of neck stiffness (69% of culture proven cases had neck stiffness relative to 48% in culture negative cases))</i>
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Unclear <i>(Unclear interval between index test and reference standard)</i>

3

4 **Study details**

Country/ies where study was carried out	France
Study type	Two-gate, cross-sectional (retrospective) DTA study. Adults hospitalized with a confirmed diagnosis of bacterial meningitis (in medical records) compared with adults hospitalized with a confirmed diagnosis of viral meningitis (in medical records).
Study dates	Bacterial meningitis: January 1982 - March 2005 Viral meningitis: June 1996 - January 2003
Inclusion criteria	Adults aged over 16 years hospitalized at the participating hospital with a diagnosis of community-acquired bacterial meningitis or viral meningitis recorded in the hospital discharge diagnostic database.
Exclusion criteria	Bacterial meningitis: Patients with mycobacterial meningitis or with bacterial pathogens associated with contamination Viral meningitis: Receipt of antibiotics within 4 days before lumbar puncture, concurrent bacterial infection.
Patient characteristics	N=144 Bacterial meningitis (n=90 analysed): Age (in years): Mean 49.7 (SD=20.5). Causative organisms: <i>S. pneumoniae</i> (44/90; 49%); <i>N. meningitidis</i> (19/90; 21%); <i>Listeria monocytogenes</i> (6/90; 7%); other streptococci (7/90; 8%); <i>Staphylococcus aureus</i> (5/90; 6%); other bacteria (9/90; 10%) Viral meningitis (n=54 analysed): Age (in years): Mean 34.9 (SD=14.0). n=28 (52%) had proportion of CSF neutrophils greater than 35%; and n=26 (48%) CSF PMN <35%.

Index test(s)	<p>Signs and symptoms (taken from medical records):</p> <ul style="list-style-type: none"> (a) Presence of a least 1 sign of severity at presentation (altered mental status; focal neurological deficits; seizures at or before presentation; or shock) (b) Altered mental status (defined as Glasgow Coma Scale [GCS] score <14) (c) Focal neurological deficits (d) Seizures at or before presentation (e) Shock <p>Data cannot be extracted for the following signs/symptoms as missing data and N per arm is not reported: duration of symptoms (<24 hours); headache; nausea/vomiting; photophobia; neck stiffness.</p>
Reference standard(s)	<p>Patients were considered to have bacterial meningitis if they fulfilled 2 of the following:</p> <ul style="list-style-type: none"> (a) a CSF Gram-stained smear positive for bacterial pathogen (b) CSF pleocytosis (>7 white blood cells/mm³) and a positive blood culture (c) a positive CSF culture for bacterial pathogen (d) a positive CSF latex agglutination test or PCR assay for <i>N. meningitidis</i>. <p>Bacterial pathogens identified in both CSF and blood cultures (n=61; 67.8%); CSF culture alone (n=24; 26.7%); blood culture alone (n=4; 4.4%); CSF latex agglutination and PCR positive for <i>N. meningitidis</i> (n=1; 1.1%).</p> <p>Patients were considered to have viral meningitis if they fulfilled the following:</p> <ul style="list-style-type: none"> (a) a pleocytosis in the CSF of at least 7 WBC/mm³ (b) absence of any bacterial growth on culture of the CSF

	(c) rapid and benign clinical course
	(d) no aetiology other than viral infection.
Duration of follow-up	Not reported
Sources of funding	Not reported
Other information	20/90 of those with bacterial meningitis received antibiotics before referral. 10/90 of those with bacterial meningitis (and none of those with viral meningitis) were immunocompromised (defined by history of splenectomy, use of immunosuppressive drugs, or infection by HIV).

1 Abbreviations: CSF: cerebrospinal fluid; DTA: diagnostic test accuracy; HIV: human immunodeficiency virus; N. Meningitidis: Neisseria Meningitidis; PCR: positive polymerase
2 chain reaction; PMN: polymorphonuclear; S. pneumoniae: Streptococcus pneumoniae; WBC: white blood count

4 **Study details**

Country/ies where study was carried out	Greece
--	--------

Study type	Single-gate, cross-sectional DTA study
Study dates	December 2000 to December 2001
Inclusion criteria	Children aged 1 month to 14 years who underwent diagnostic lumbar puncture for infectious meningitis during the study period after being admitted to the participating hospital (2nd Department of Pediatrics of Athens Medical School)
Exclusion criteria	Patients who were administered antibiotics within 72 hours before evaluation; those who underwent a neurosurgical procedure or lumbar puncture for reasons other than the diagnosis of infectious meningitis; those with known immunodeficiency
Patient characteristics	<p>N=145</p> <p>Meningococcal meningitis (n=40):</p> <p>Age in months (mean; standard deviation in parentheses): 75.3 (39.7)</p> <p>Sex: male: 25 (62.5%); female: 15 (37.5%)</p> <p>Viral meningitis/no meningitis (n=105):</p> <p>Viral meningitis (n=32); No meningitis (n=73)</p> <p>Age in months (mean; standard deviation in parentheses): 50.3 (53.3)</p> <p>Sex: male: 54 (51%); female: 51 (49%)</p>
Index test(s)	<p>Signs and symptoms (recorded in a pre-coded questionnaire on admission):</p> <p>(a) Respiratory symptoms</p> <p>(b) Gastrointestinal symptoms</p> <p>(c) Vomiting</p>

	(d) Neck stiffness
	(e) Kernig's sign
	(f) Brudzinski's sign
	(g) Hemorrhagic rash
	(i) Headache
Reference standard(s)	Bacterial meningitis, which was in all cases meningococcal, was confirmed by blood or CSF culture and/or Gram stain, or by PCR for meningococcus
Duration of follow-up	Not reported
Sources of funding	Not reported (authors declared no conflicts of interest)

1 *Abbreviations: CSF: cerebrospinal fluid; DTA: diagnostic test accuracy; PCR: positive polymerase chain reaction*

2 Outcomes

3 Signs and symptoms of meningococcal meningitis

Outcome	N = 145
Respiratory symptoms	TP 5; FP 22; FN 35; TN 83
Custom value	
Gastrointestinal symptoms	TP 27; FP 50; FN 13; TN 55
Custom value	
Vomiting	TP 24; FP 35; FN 16; TN 70
Custom value	
Neck stiffness	TP 36; FP 54; FN 4; TN 51
Custom value	

Outcome	N = 145
Kernig's sign	TP 4; FP 8; FN 36; TN 97
Custom value	
Brudzinski's sign	TP 7; FP 8; FN 33; TN 97
Custom value	
Hemorrhagic rash	TP 4; FP 10; FN 36; TN 95
Custom value	
Headache Only reported for children aged >1 year	TP 30; FP 45; FN 5; TN 27
Custom value

4 **Study details**

Country/ies where study was carried out	US
Study type	Single-gate, cross-sectional (retrospective) DTA study

Study dates	January 1978 - October 1979
Inclusion criteria	Children aged 6 months to 6 years, presenting at the emergency room with a first episode of seizure and fever.
Exclusion criteria	Children who did not undergo lumbar puncture and insufficient follow-up data available (telephone follow-up or chart review did not document the outcome of the acute illness); children with a predisposition to meningitis (for example, those who had a CNS shunt).
Patient characteristics	<p>N=241</p> <p>Meningitis (n=13)</p> <p>Age in months: Mean 22 (SD not reported)</p> <p>Sex: male 6 (46%); female: 7 (54%)</p> <p>No meningitis/febrile seizures (n=228)</p> <p>Age in months: Mean 23 (SD not reported)</p> <p>Sex: male 144 (63%); female: 84 (37%)</p>
Index test(s)	<p>Signs and symptoms (taken from medical records):</p> <p>(a) Visit to a physician in the 48 hours prior to the seizure</p> <p>(b) Seizure at presentation</p> <p>(c) Type of seizure (focal versus generalized)</p> <p>(d) Presence of rash/petechiae, cyanosis, hypotension, or grunting respirations</p> <p>(e) Abnormal neurologic findings (defined as stiff neck, increased tone, deviated eyes, ataxia, no response to voice, inability to fix and follow, no response to painful stimuli, positive doll's eye sign, floppy muscle tone, nystagmus, and bulging or tense</p>

	fontanelle) (f) Presence of at least 1 factor (visit to physician within 48 hours or focal type of seizure) (g) Presence of at least 1 factor (visit to physician within 48 hours or abnormal neurologic finding) (h) Presence of at least 1 factor (visit to physician within 48 hours or seizure at presentation) (i) Presence of at least 1 factor (focal type of seizure or presence of abnormal physical finding [rash/petechiae, cyanosis, hypotension, or grunting respirations]) (j) Presence of at least 1 factor (focal type of seizure or abnormal neurologic findings) (k) Presence of at least 1 factor (visit to physician within 48 hours; seizure at presentation; focal type of seizure; presence of abnormal physical finding [rash/petechiae, cyanosis, hypotension, or grunting respirations]; abnormal neurologic findings)
Reference standard(s)	CSF pleocytosis (11/13 of children with CSF pleocytosis had positive CSF bacterial cultures)
Duration of follow-up	Not reported
Sources of funding	Not industry funded
Other information	Very small number of participants with bacterial meningitis enrolled in the study

1 Abbreviations: CSF: cerebrospinal fluid; CNS: central nervous system; DTA: diagnostic test accuracy; SD: standard deviation

2

3 Outcomes

4 Signs and symptoms of bacterial meningitis

Outcome	N = 241
Visit to a physician in the 48 hours prior to the seizure	TP 6; FN 7; FP 37; TN 191
Custom value	

Outcome	N = 241
Seizure at presentation	TP 3; FN 10; FP 9; TN 219
Custom value	
Type of seizure (focal)	TP 5; FN 8; FN 20; TN 208
Custom value	
Presence of rash/petechiae, cyanosis, hypotension, or grunting respirations	TP 3; FN 10; FP 10; TN 218
Custom value	
Abnormal neurologic findings	TP 12; FN 1; FP 37; TN 191
Custom value	
Presence of at least 1 factor (visit to physician within 48 hours or focal type of seizure)	TP 9; FN 4; FP 50; TN 178
Custom value	
Presence of at least 1 factor (visit to physician within 48 hours or abnormal neurologic finding)	TP 13; FN 0; FP 66; TN 162
Custom value

4 **Study details**

Country/ies where study was carried out	US
Study type	Single-gate, cross-sectional (retrospective) DTA study
Study dates	June 1979 to June 1980
Inclusion criteria	Paediatric patients (under 18 years of age) who had undergone a lumbar puncture
Exclusion criteria	Not reported
Patient characteristics	N=168 Bacterial meningitis (n=10): Age in months (mean; range in parentheses): 7.8 (9 days to 18 months) Sex: male: 6 (60%); female: 4 (40%) Positive CSF culture (n=9): H. influenzae B (n=3); H. influenzae nontypeable (n=1); S. pneumoniae meningitis (n=2); N.

	<p>meningitidis C (n=1); group D streptococcus (n=1); <i>Listeria monocytogenes</i> (n=1)</p> <p>Other type of meningitis/no meningitis (n=158):</p> <p>Bacteremia only (positive blood cultures and normal CSF [no bacterial or aseptic meningitis]), n=3; Aseptic meningitis (abnormal CSF but negative CSF culture results), n=10; No meningitis (negative CSF cultures, normal CSF findings by judges, and no bacteremia), n=145</p> <p>Age in months (mean; range in parentheses): 7.3 (4 days to 9 years)</p> <p>Sex: male: 93 (59%); female: 65 (41%)</p>
Index test(s)	<p>Signs and symptoms taken from medical records:</p> <ul style="list-style-type: none"> (a) Fever (b) Upper respiratory symptoms (c) Diarrhoea (d) Loss of appetite (e) Vomiting (d) Seizures (e) Constipation (f) Reduced consciousness, defined as non-alert appearance (converted data for 'alert') (g) Irritable

	(h) Lethargic (i) Toxic or ill (j) Petechiae
Reference standard(s)	Bacterial meningitis diagnosed based on positive bacterial cultures of the CSF, regardless of blood culture results. For 1/10 of this group, CSF culture was negative, but the patient developed a subdural effusion and a mild communicating hydrocephalus. Blood culture yielded <i>H. influenzae</i> B, and CSF was interpreted as abnormal by two independently working expert judges.
Duration of follow-up	Not reported
Sources of funding	Not reported
Other information	Very small number of participants with bacterial meningitis enrolled in the study

1 Abbreviations: CSF: cerebrospinal fluid; DTA: diagnostic test accuracy; *H. influenzae* type B: *Haemophilus influenzae* type b (Hib); *H. influenzae* nontypeable: *Haemophilus*

Study type	Single-gate, cross-sectional (retrospective) DTA study
Study dates	January 2002 to December 2006
Inclusion criteria	Adults presenting to the emergency department and admitted to the infectious disease department or intensive care unit with a discharge diagnosis of meningitis, viral or bacterial (including meningococcal meningitis)
Exclusion criteria	Glasgow Coma Scale (GCS) not clearly recorded; comorbidities, such as vascular or essential brain chronic disease (dementia); medications that could impact the GCS evaluation; workup could not be completed (including lumbar puncture could not be performed) because of contraindications
Patient characteristics	<p>N=202</p> <p>Bacterial meningitis (n=40):</p> <p>Age in years (mean; standard deviation in parentheses): 55.7 (18.2)</p> <p>Immunocompromised n=6 (15%)</p> <p>Viral meningitis (n=162):</p> <p>Age in years (mean; standard deviation in parentheses): 39.5 (17.4)</p> <p>Immunocompromised n=10 (6%)</p>

	Whole sample (N=202): Sex: male: 105 (52%); female: 97 (48%)
Index test(s)	Signs and symptoms (recorded from physical examination performed by the emergency physicians in the emergency department, and taken from medical record): (a) Reduced consciousness, defined as GCS score <15 (b) Kernig or Brudzinski signs (c) Neck stiffness (d) Kernig or Brudzinski signs or neck stiffness (e) Neurological complaints, including seizure and focal neurological deficits (f) Severe sepsis or shock (Severe sepsis was defined as the presence of sepsis and one or more organ dysfunctions, or hypoperfusion with lactic acidosis. Septic shock was defined as the presence of sepsis and refractory hypotension)
Reference standard(s)	Lumbar puncture performed on all participants. The diagnosis of meningitis and its aetiology were established by the infectious disease specialist or the intensivist based on all laboratory and instrumental investigations performed during the hospital stay, and on the basis of hospital course.
Duration of follow-up	Not reported
Sources of funding	Not reported
Other information	No details on bacterial aetiology of patients diagnosed with bacterial meningitis
1	<i>Abbreviations: DTA: diagnostic test accuracy; GCS: Glasgow Coma Scale</i>
2	
3	Outcomes
4	Signs and symptoms of bacterial meningitis
Outcome	N = 202

Outcome	N = 202
Reduced consciousness	TP 27; FP 36; FN 13; TN 126
Custom value	
Kernig or Brudzinski signs	TP 19; FP 51; FN 21; TN 111
Custom value	
Neck stiffness	TP 28; FP 89; FN 12; TN 73
Custom value	
Kernig or Brudzinski signs or neck stiffness	TP 28; FP 99; FN 12; TN 63
Custom value	
Neurological complaints	TP 10; FP 25; FN 30; TN 137
Custom value	
Severe sepsis or shock	TP 24; FP 0; FN 16; TN 162

3 **Critical appraisal - NGA Critical appraisal - QUADAS-2**

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Unclear <i>(Consecutive sample enrolled but only adults diagnosed with bacterial meningitis or viral meningitis were included)</i>
Patient selection:	Are there concerns that included	Low <i>(Some patients were immunocompromised (15% of bacterial meningitis group and 6% of</i>

Section	Question	Answer
applicability	patients do not match the review question?	<i>viral meningitis group) but not downgraded for indirectness as below threshold (25%)</i>
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	Low <i>(Index tests were interpreted without knowledge of the reference standard, and sufficient detail provided on how signs and symptoms were defined and measured)</i>
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	High <i>(Lumbar puncture performed on all participants. The diagnosis of meningitis and its etiology were established by the infectious disease specialist or the intensivist based on all laboratory and instrumental investigations performed during the hospital stay, and on the basis of hospital course. No details on proportion of population diagnosed with CSF culture)</i>
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Unclear <i>(Unclear interval between index test and reference standard)</i>

4 **Study details**

Country/ies where study was carried out	US
Study type	Single-gate, cross-sectional (retrospective) DTA study
Study dates	1969 to 1978
Inclusion criteria	Older children and adults discharged from the participating hospital with a diagnosis of acute meningitis. Data only analysed for those with bacterial or aseptic meningitis.
Exclusion criteria	Children aged less than 12 years
Patient characteristics	<p>N=59</p> <p>Bacterial meningitis (n=25):</p> <p>Age in years (mean): 53.6</p> <p>Sex: male: 13 (52%); female: 12 (48%)</p> <p>Bacterial aetiology: Pneumococcal (n=9; 36%); meningococcal (n=2; 8%); Pseudomonas species (n=1; 4%); S. epidermidis (n=1; 4%); Gamma-streptococcus (n=1; 4%); Alpha-streptococcus (n=1; 4%); H. influenzae (n=1; 4%); unknown (n=9; 36%).</p> <p>Aseptic meningitis (n=34):</p> <p>Age in years (mean): 28.6</p> <p>Sex: male: 13 (38%); female: 21 (62%)</p>

Index test(s)	Signs and symptoms (recorded at presentation, and taken from medical records): (a) Fever (defined as temperature >38.9°C) (b) Headache (c) Nuchal rigidity (d) Moderate or severe mentation changes (e) Focal neurologic signs
Reference standard(s)	Bacterial meningitis: Known aetiology - positive result on CSF gram stain or a CSF culture and/or blood culture positive for pathogenic bacterial species. Unknown aetiology - negative CSF gram stain and negative CSF culture or blood cultures, but had CSF lab results showing a total WBC of more than 1,000 per cubic mm with more than 50% PMN's, plus total protein greater or equal to 80mg/100ml and/or glucose less than or equal to 40mg/100ml.
Duration of follow-up	Not reported
Sources of funding	Not reported
Other information	Study includes 9/25 diagnoses made without positive culture Papilledema also reported as an outcome but no events in either arm

1 Abbreviations: CSF: cerebrospinal fluid; DTA: diagnostic test accuracy; *H. influenzae*: *Haemophilus influenzae*; PMN: polymorphonuclear; *S. epidermidis*: *Staphylococcus*
 2 *epidermidis*; WBC: white blood count
 3

3 **Critical appraisal - NGA Critical appraisal - QUADAS-2**

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Unclear <i>(Consecutive sample enrolled but excluded children aged under 12 years, and those with meningitis types other than bacterial or aseptic (tuberculosis, fungal, and unknown) were not included in the analysis)</i>
Patient selection: applicability	Are there concerns that included patients do not match the review question?	Low

Section	Question	Answer
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	Unclear <i>(Index tests were interpreted without knowledge of the reference standard (data on signs/symptoms recorded at presentation). However, limited detail provided on how signs and symptoms were defined and measured, and retrospective study over 10 years with various investigators assessing signs and symptoms without clear definitions)</i>
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	High <i>(Study includes 9/25 diagnoses made without positive culture)</i>
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Unclear <i>(Unclear interval between index test and reference standard)</i>

4 **Study details**

Country/ies where study was carried	Denmark
--	---------

out	
Study type	Single-gate, cross-sectional (retrospective) DTA study
Study dates	May 1980 to April 1987
Inclusion criteria	Children, aged under 16 years, admitted for observation for suspected meningitis to the paediatric ward.
Exclusion criteria	Not reported
Patient characteristics	<p>N=160</p> <p>Purulent meningitis (n=17):</p> <p>Bacterial aetiology: H. influenzae (n=2; 12%); N. meningitidis (n=8; 47%); S. pneumoniae (n=2; 12%); unknown organisms (n=2; 12%); n=3 (18%) with PM due to N. meningitidis were admitted with a different diagnosis</p> <p>Other types of meningitis/non-meningitis (n=143):</p> <p>Aseptic meningitis (n=5; 3%); aseptic meningitis with parotitis (n=10; 7%); parotitis (uncomplicated; n=2; 1%); encephalitis/radiculomyelitis (n=5; 3%); upper respiratory tract infections (n=45; 31%); fever of unknown origin (n=42; 29%); pneumonia (n=21; 15%); gastroenteritis (n=4; 3%); measles (n=4; 3%); urinary tract infection (n=2; 1%); other (n=3; 2%)</p> <p>Total sample (N=160):</p> <p>Age in years (median; lower and upper quartiles parentheses): 5 (2-9)</p> <p>Sex: male: 111 (69%); female: 49 (31%)</p> <p>78/160 (49%) underwent lumbar puncture</p>

Index test(s)	Signs and symptoms (taken from referral letters from GPs and hospital discharge letters): (a) Duration of symptoms of 24 hours or less (b) Fever (c) Neck stiffness (d) Kernig's sign (e) Rash (f) Petechiae (g) Nausea/vomiting (h) Impaired consciousness (i) Convulsions
Reference standard(s)	Criteria for diagnosis not reported. All those with purulent meningitis underwent a lumbar puncture (and N=61, 43%, of those in the control group underwent LP)
Duration of follow-up	Not reported
Sources of funding	Not reported
Other information	Very small number of participants with purulent meningitis enrolled in the study

1 Abbreviations: DTA: diagnostic test accuracy; GP: general practitioner; H. influenzae type B: Haemophilus influenzae type b (Hib); LP: lumbar puncture; N. Meningitidis: Neisseria
2 Meningitidis; PM: Purulent meningitis; S. pneumoniae: Streptococcus pneumoniae

3 **Study details**

Country/ies where study was carried out	Netherlands
Study type	Single-gate, cross-sectional (retrospective) DTA study
Study dates	1988 to 1995 (data collected on patients between 1996 and 1998 used to create a validation set but signs and symptoms not reported for these later patients)
Inclusion criteria	Babies and children aged from 1 month to 15 years visiting the emergency department of the participating hospital during the study dates; who were retrospectively coded as having meningeal signs
Exclusion criteria	Patients with a history of severe neurological disease; ventricular drain; those referred from other hospitals
Patient characteristics	<p>N=286</p> <p>Bacterial meningitis (n=84):</p> <p>Age in years (mean; 95% confidence interval in parentheses): 3.6 (2.8–4.3)</p> <p>Sex: male: 42 (50%); female: 42 (50%)</p> <p>Other types of meningitis/non-meningitis (n=202):</p> <p>Age in years (mean; 95% confidence interval in parentheses): 3.5 (3.0–4.0)</p>

	Sex: male: 133 (66%); female: 69 (34%)
	Viral/aseptic meningitis (n=34; 17%); pneumonia (n=20; 10%); other bacterial infections, including septicaemia, urinary tract infections and gastroenteritis (n=8; 4%); self-limiting diseases, upper respiratory tract infections, non-specified viral infection and myogenic torticollis (n=140; 69%)
Index test(s)	Signs and symptoms taken from medical records (based on clinical history and physical examination): (a) Complex convulsions (b) Disturbed consciousness (defined as reaction to pain only or no reaction at all) (c) Cyanosis (d) Petechiae or ecchymoses (e) Meningeal irritation (defined as presence of Brudzinski sign I or II, Kernig sign, tripod phenomenon or neck stiffness in children aged over 1 year, and in children aged 1 year or under one of the previous signs or irritability during manipulation of the head or legs by the paediatrician, or a bulging fontanelle) (f) Focal neurological disorders
Reference standard(s)	Bacterial meningitis defined as leucocyte count of >5 cells ul-1 in the CSF, with positive bacterial cultures of CSF or blood.
Duration of follow-up	Not reported
Sources of funding	Not reported
Other information	Data could not be extracted for signs/symptoms with missing data as only overall percentage of sample reported and n's per group unclear

1 Abbreviations: CSF: cerebrospinal fluid; DTA: diagnostic test accuracy

3 **Critical appraisal - NGA Critical appraisal - QUADAS-2**

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Low (<i>Consecutive sample enrolled, and study avoided inappropriate exclusions</i>)
Patient selection: applicability	Are there concerns that included patients do not match the review question?	Low

Section	Question	Answer
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	Unclear <i>(No information about whether index tests were interpreted without knowledge of the reference standard. Some detail provided on how signs and symptoms defined, however, retrospective study over 7 years and definitions not systematically quantified)</i>
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	High <i>(Bacterial meningitis defined as leucocyte count of >5 cells ul-1 in the CSF, with positive bacterial cultures of CSF or blood. No details on proportion of population diagnosed with CSF culture)</i>
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Unclear <i>(Unclear interval between index test and reference standard)</i>

4 **Study details**

Country/ies where study was carried	US
--	----

out	
Study type	Single-gate, cross-sectional DTA study
Study dates	August 1985 to February 1988
Inclusion criteria	Children undergoing lumbar puncture, after examination by 1/6 pediatric emergency attending physicians in the emergency department of the participating hospital during the study period
Exclusion criteria	Not reported
Patient characteristics	<p>N=172</p> <p>Bacterial meningitis (n=53):</p> <p>Age in months (mean; range in parentheses): 30 (3 weeks to 16 years)</p> <p>Bacterial aetiology: H. influenzae (n=35; 66%); S. pneumoniae (n=12; 23%); N. meningitidis (n=3; 6%); Group B Streptococcus (n=2; 4%); Escherichia coli (n=1; 2%)</p> <p>Aseptic meningitis (n=119):</p> <p>Age in months (mean; range in parentheses): 31 (1 week to 17 years)</p>
Index test(s)	<p>Signs and symptoms (recorded by paediatric emergency attending physicians in the emergency department):</p> <p>(a) Bulging fontanelle</p> <p>(b) Nuchal rigidity, defined as neck stiffness with active and/or passive neck flexion</p> <p>(c) Kernig's sign, defined as complete extension of the leg was not possible or produced significant discomfort</p> <p>(d) Brudzinski's sign, defined as passive neck flexion resulted in flexion of the legs (hips and knees)</p> <p>(e) Nuchal rigidity or Kernig's sign or Brudzinski's sign</p>

	(f) Toxic/moribund. Toxic defined as lethargic, inconsolable, and lack of interest in environment and significant alterations in respiratory or heart rates or decreased peripheral perfusion. Moribund defined as unarousable with poor peripheral perfusion and unstable vital signs
	(g) Lethargic/comatose
	(h) Shock
Reference standard(s)	CSF culture, CSF latex agglutination or Gram stain
Duration of follow-up	Not reported
Sources of funding	Not reported

Abbreviations: CSF: cerebrospinal fluid; DTA: diagnostic test accuracy; H. influenzae type B: Haemophilus influenzae type b (Hib); N. Meningitidis: Neisseria Meningitidis; S. pneumoniae: Streptococcus pneumoniae
